2 Lab sheet 3

This third lab gets you to work with big- Θ classes and practically check the efficiency of sorting algorithms by testing them on randomly generated arrays.

Marks (max 5): Question 1: 1.5 | Question 2: 1 | Questions 3-7: 0.5 each

2.1 Question 1 (does not require coding)

For each of the following expressions, find if they are $\Theta(1)$, $\Theta(\log n)$, $\Theta(n)$, $\Theta(n\log n)$, $\Theta(2)$, $\Theta(n2022)$ or $\Theta(2n)$: 1. $500 + 0.5n + 45\log n$ 2. 5000 3. $42 + n\log n + 5\log n + 50$ 4. $5n\log n + 2n + 300n2020n2$

Find the complexity, in terms of a simple big- Θ class, of the following expression:

```
5(\log n)13 + 300n3 + 30n\log n + 100
```

Finally, consider the following function that counts the duplicate elements inside an array.

```
def countDups(A):
    B = A[:]
    selectionSort(B)
    dups = 0
    for i in range (1,len(B)):
        if B[i] == B[i-1]: dups += 1
    return dups
```

Explain, in terms of big- Θ , what is the worst-case time complexity of countDups as a function of the size of the array A. Note here that the line B=A[:] is the same B=A[0:len(A)], that is, it creates a copy of A and stores it in B.

2.2 Question 2

Write a version of insertion sort that works constructively, i.e. returns a new sorted array and leaves the original array unchanged.

For example, if we call this version insertionSortC, and run the following code

```
A = [30, 25, 67, 99, 8, 16, 28, 63, 12, 20]

B = insertionSortC(A1)
```

```
print("Original array is: ",A)
    print("Sorted is: ",B)
    we get this printout:
    Original array is: [30, 25, 67, 99, 8, 16, 28, 63, 12, 20]
    Sorted is: [8, 12, 16, 20, 25, 28, 30, 63, 67, 99]
    Test your code in at least 5 arrays of your choosing, including the empty array.
[]: def insertionSortC(arr):
         # Create a copy of the input array to avoid modifying the original
         sorted arr = arr.copy()
         # Traverse through the array starting from the second element
         for i in range(1, len(sorted_arr)):
             key = sorted_arr[i]
             j = i - 1
             # Move elements of sorted_arr[0..i-1] that are greater than key
             # one position ahead of their current position
             while j >= 0 and key < sorted_arr[j]:</pre>
                 sorted_arr[j + 1] = sorted_arr[j]
                 i -= 1
             sorted_arr[j + 1] = key
         return sorted_arr
     test arrays = [
         [30, 25, 67, 99, 8, 16, 28, 63, 12, 20],
         [5, 4, 3, 2, 1],
         [],
         [10, 20, 30, 40, 50],
         [99, 88, 77, 66, 55, 44, 33, 22, 11, 0]
     ]
     for test_arr in test_arrays:
         sorted_arr = insertionSortC(test_arr)
         print(f"Original array is: {test_arr}")
         print(f"Sorted is: {sorted_arr}")
    Original array is: [30, 25, 67, 99, 8, 16, 28, 63, 12, 20]
    Sorted is: [8, 12, 16, 20, 25, 28, 30, 63, 67, 99]
    Original array is: [5, 4, 3, 2, 1]
    Sorted is: [1, 2, 3, 4, 5]
    Original array is: []
    Sorted is: []
    Original array is: [10, 20, 30, 40, 50]
```

Sorted is: [10, 20, 30, 40, 50]

```
Original array is: [99, 88, 77, 66, 55, 44, 33, 22, 11, 0]
Sorted is: [0, 11, 22, 33, 44, 55, 66, 77, 88, 99]
```

2.3 Question 3

For this question you may use Python's built-in function for producing random numbers. If you import Python's built-in module random by calling:

```
import random
```

then random.randint(low,high) will return a random integer in the range low to high inclusive (i.e. an integer with an equal chance of it being any of the numbers in that range). Use this to write a Python function:

```
def randomIntArray(s,n)
```

which returns an array of length s that in each position has a random integer in the range 0 to n.

For example, running randomIntArray(5,10) we may get back the array [6, 2, 3, 9, 1], or [6, 10, 6, 1, 1], etc.

```
[]: import random

def randomIntArray(s, n):
    # Create an array of length s with random integers in the range 0 to n
    return [random.randint(0, n) for _ in range(s)]

# Example usage
result = randomIntArray(5, 10)
print(result)
```

[2, 8, 9, 7, 2]

2.4 Question 4

Python's built-in function time() in the module time returns the current time in the form of the number of seconds since 0.00am on 1st January 1970. So, code of the form:

```
t = time.time()
<operation>
t = time.time()-t
```

will set t to the time it takes to perform coperation. As time.time() returns a floating point number rather than an integer, this could be a fraction of a second.

Use this to write a Python function:

```
def appendTime(A,v)
```

which takes an array A a value v as input and creates a new array with the same elements as A but with v appended at its end (for example, you can use the code of the function append that we saw in Lecture 1). The function then returns the new array and the time it took to create it. For example:

```
(B,t) = appendTime(A,42)
    print("Time taken to append is: ",t)
    print("The new array is: ",B)
    we can get the printout:
    Time taken to append is: 8.58306884765625e-06
    The new array is: [30, 25, 67, 99, 8, 16, 28, 63, 12, 20, 42]
    Test your code in at least 5 arrays, with lengths 0, 10, 100, 1000 and 10000 respectively.
[]: import random
     import time
     def appendTime(A, v):
         start_time = time.time()
         B = A.copy()
         B.append(v)
         end_time = time.time()
         elapsed_time = end_time - start_time
         return B, elapsed_time
     tests = (randomIntArray(i, 100) for i in [0, 10, 100, 1000, 10000])
     for A in tests:
         (B, t) = appendTime(A, 42)
         print("Time taken to append is:", t)
         print("The new array is:", B)
         print()
    Time taken to append is: 1.1920928955078125e-06
    The new array is: [42]
    Time taken to append is: 9.5367431640625e-07
    The new array is: [22, 31, 7, 44, 97, 50, 54, 14, 55, 29, 42]
    Time taken to append is: 9.5367431640625e-07
    The new array is: [32, 18, 21, 21, 13, 22, 4, 99, 5, 1, 28, 79, 91, 96, 61, 69,
    66, 44, 31, 81, 15, 69, 50, 73, 11, 78, 39, 82, 77, 78, 33, 92, 9, 36, 80, 42,
    99, 34, 22, 7, 34, 42, 77, 73, 89, 22, 35, 68, 73, 100, 20, 32, 38, 29, 15, 25,
    47, 10, 53, 68, 6, 62, 86, 19, 94, 55, 29, 84, 16, 42, 8, 88, 23, 43, 0, 69, 74,

    62, 60, 63, 42]
    Time taken to append is: 2.1457672119140625e-06
    The new array is: [94, 85, 97, 93, 82, 57, 52, 41, 65, 6, 0, 28, 18, 23, 72, 1,

2.5 Question 5

Write a Python method:

```
def sortTimeUsing(sortf,A)
```

which returns the time taken to sort the array A, but does the sorting using the sorting function passed as argument sortf. This uses the concept of passing a function as an argument that was introduced in Question 6 of Lab 1.

Use this to compare the time taken to sort using selection sort with the time taken to sort using insertion sort, the code of which you can find on the lecture slides, on some example arrays.

```
[]: import time
     def sortTimeUsing(sortf, A):
         start_time = time.time()
         sorted_arr = sortf(A)
         end_time = time.time()
         elapsed_time = end_time - start_time
         return sorted_arr, elapsed_time
     def selectionSort(arr):
         n = len(arr)
         for i in range(n):
             min index = i
             for j in range(i + 1, n):
                 if arr[j] < arr[min_index]:</pre>
                     min_index = j
             arr[i], arr[min_index] = arr[min_index], arr[i]
         return arr
     def insertionSort(arr):
         for i in range(1, len(arr)):
             key = arr[i]
```

```
while j >= 0 and key < arr[j]:</pre>

2.6 Question 6

Use the method randomIntArray from Question 3 to provide arrays to be sorted by sortTimeUsing. This will enable you to test how long it takes to sort an array much longer than one you could type in yourself. Then, fill in the following table (but see Note).

array length	10	100	1000	104	105	106
selection sort		0.00000	6 0.000199	0.020896	2.085683	Timeout
time (sec) insertion sort		0.00000	4 0.000200	0.021699	2.197901	Timeout
time (sec)						

For each array length, produce a random array of that length, sort it via sortTimeUsing using selection sort and insertion sort (make sure you sort the same array twice!), and fill in the table the corresponding times.

Note: sorting arrays of length greater than 105 may make your computer run out of memory and hang. For that reason, you can skip filling in the last column in the table. If you do want to fill it in, make sure you save everything before and be ready to hard-restart your computer!

It would also make sense to stop a test if it runs over a few minutes and fill in "timeout" in the respective column.

```
[]: import random

def randomIntArray(s, n):
    return [random.randint(0, n) for _ in range(s)]

2.7 Question 7

Write a version of insertion sort where the insert function uses binary search. More precisely, to insert a value v in an array A where the part A[:i] is sorted, the insert function will: - use binary search to find the position in A[:i+1] where v needs to be inserted - move elements from that position one place to the right and insert v

What is the complexity of this version of insertion sort: O(n2) or O(nlogn)?

```
[]: def binary_search(arr, v, start, end):
         while start < end:
             mid = start + (end - start) // 2
             if arr[mid] < v:</pre>
                 start = mid + 1
             else:
                 end = mid
         return start
     def insertion_sort_with_binary_search(arr):
         for i in range(1, len(arr)):
             key = arr[i]
             j = i - 1
             # Find the position to insert key using binary search
             insert_position = binary_search(arr, key, 0, j + 1)
             # Shift elements to the right to make space for key
             for k in range(i, insert_position, -1):
                 arr[k] = arr[k - 1]
             # Insert key at the correct position
             arr[insert_position] = key
         return arr

The version of insertion sort that uses binary search to find the position for inserting a value v into an array A has a time complexity of $O(n^2)$.

While the binary search for finding the correct position to insert v reduces the number of comparisons compared to the traditional insertion sort (which performs linear searches), the subsequent shifting of elements to make room for v still takes O(n) time on average for each insertion.

This is because, in the worst case, the binary search can locate the correct position for v in $O(\log n)$ time, but shifting the elements to the right takes O(n) time to create the space for the insertion.

As a result, the overall time complexity remains $O(n^2)$ for this version of insertion sort, making it less efficient than sorting algorithms with $O(n \log n)$ time complexity, such as quicksort or mergesort.
